The architectural sector has greatly developed in the last few years with the advent of technical advancements that are increasingly paving way for smarter and more effective solutions. Today, this growing sector demands that projects are successfully completed within the stipulated limits of time and budgets with no compromise in quality. The architectural industry has witnessed much advancement in technology and new innovations, all of which focus on completing construction at a faster rate and delivering high performance. A typical industry trend is the increased use of the latest IT technologies for pacing up the work. Cutting edge technologies like 3D rendering, CAD drafting and BIM (Building Information Modeling) are being used for raising the efficiency level of engineering and designing of construction industry.

3D rendering is one of the most popular and widely used technologies advocated by Architects, Design Engineers and Builders to deliver high-performance and efficient construction projects within the constraints of time and costs.

3D rendering is the art of visualizing a construction project virtually, before the construction begins in the real world. Using 3D rendering, one is able to view the exterior and interior of the development from all angles without spending a single penny over building it. 3D rendering greatly influences the efficiency, reliability and presentation of the proposed building owing to its single greatest advantage of viewing and analyzing it in a single effort. 3D rendering gives an immersive experience through a virtual world by allowing its users to practically engage with the model, though in a simulated environment, but which would be too costly an affair if implemented and experienced in a real world.

3D rendering is one of the preferred technologies for creating engaging user experiences through making realistic manifestations of proposed development and making it easier to view and understand. 3D rendering facilitates the idea of having an opportunity to conceptualize how a final design would look like. This is the best time for an architect or engineer to study his design from all angles. He can identify possible errors in the design as may be the case when there are several inputs from various experts in the design preparation. Not only detect, but he can also make necessary modifications in the design so that is completely error-free and perfect.

Timely identification and alterations in the design can save a lot of time and efforts when the actual construction begins at a later stage. 3D rendering has gained a lot of importance in the architectural industry in recent years owing to its improved features and advantages that it offers to the users. It improves the efficiency of design, reduces the disparity between client requirement and the architect's understanding of it and also improves the presentation and salability of the design to a very great extent.

3D rendering is slowly picking up amidst the challenges to develop 3D technologies. However, given the time, resources and focus on developing it further to achieve greater use and success, it is anticipated to have considerable advances in the upcoming years.
